A TREE SHELTER

The present invention relates to a tree shelter and, in particular, to a degradable tree shelter and preferably one
5 which is fully biodegradable.

The term "tree shelter" when used herein and in the claims should be understood as meaning a shelter suitable for use with any form of plant, either woody or herbaceous, and
10 not as only suitable for use with trees.

When young trees and shrubs are first planted, it is desirable to provide them with support and protection from damage caused by adverse weather conditions, such as high
15 winds, ground erosion and animals. Typically, this is done by means of a tree shelter which encloses at least the lower part of the tree or shrub in a tubular support.

Conventional tree shelters are typically cast from
20 photo-degradable plastics materials that are designed to degrade within three to four years. It has been found, however, that such supports do not fully degrade within the time frame but disintegrate gradually between three and ten years into separate pieces so that the unsightly remains of
25 the supports can still be present around the tree or shrub for some considerable time. As much tree and shrub planting is carried out for landscaping purposes, having disintegrating supports still visible some years after planting is undesirable and in order to remedy the situation
30 it is common practice to remove the supports after a sufficient period of time has elapsed to enable the trees or shrubs have become established. However, apart from the effort involved, an additional problem is created because the remains of the tree shelters removed from such sites have to
35 be disposed of. Typically, they end up as refuse in landfill sites where they are buried. However, as they are only photo-

- 2 -

degradable, once buried degradation will take longer and they therefore can become an environmental nuisance.

The object of the present invention is to overcome the
5 aforementioned disadvantages of conventional tree shelters.
and to provide a tree shelter which is designed to degrade
into a loose fibrous state over a predetermined time span.

According to a first aspect of the present invention
10 there is provided a tree shelter comprising a biodegradable
fibrous mat covered with a degradable resin and adapted to be
formed into a roll which can enclose at least the lower part
of a plant.

15 It will be appreciated that because the core of the
shelter comprises a biodegradable fibrous mat, once the
exterior coating of resin starts to degrade, the fibrous core
is exposed to environmental conditions and therefore also
starts to degrade. Unlike conventional photo-degradable tree
20 shelters, which tend to disintegrate into large pieces, the
fibrous nature of the tree shelter of the present invention
means that ultimately it will decompose back into a loose
fibrous state that will absorb moisture and form a beneficial
mulch around the base of the plant, unlike the large pieces
25 of conventional photo-degradable shelters, which serve no
additional purpose and tend to litter the planting area and
be carried away by the wind to form a nuisance elsewhere.

The degradable resin is preferably also fully
30 biodegradable but can be subject to other forms of
degradation in addition to or instead of biodegradation.
There are three main routes to degradation, as follows.

1. Biodegradation, wherein the material is broken down by
35 the action of bacteria, such as yeasts, and moulds. Such

- 3 -

degradation is slow in the atmosphere but more active when the material is in direct contact with soil.

2. Photo-degradation, as mentioned above, wherein ultra-violet light acts at a molecular level to breakdown the molecules of the material into smaller molecules, thus causing the material to disintegrate.
3. Moisture degradation, wherein a continual softening and hardening of a material by the action of water absorption, either above or below ground level, causes the material to disintegrate.

Preferably, the degradable resin comprises an exterior coating over the side surfaces of the fibrous mat. The resin stiffens the mat and also slows its own biodegradation, which may otherwise occur too quickly. Hence, the quantity of resin used is a factor to be taken into account when determining a required life for the shelter. For example, one for use in viniculture may only be required to last for two years prior to biodegradation. In contrast, in slow-growing forest plantations, it may be necessary to use shelters which will last for up to five years to give the sapling trees sufficient time to establish themselves before degradation. Such time spans can be substantially predetermined by choosing an appropriate resin and the thickness of the coating.

The shelter may comprise a laminate structure made from two outer sheets of resin which are bonded to and enclose the fibrous mat. Alternatively, the side surfaces of the fibrous mat can be with the resin by rolling or painting the resin on to the mat.

It will also be appreciated that the number of layers of fibres in a non-woven mat and the thickness of the yarn and

- 4 -

looseness of the weave in a woven mat will affect the overall thickness of the fibrous mat. This, in turn, will affect the length of time that the tree shelter will take to biodegrade. Hence, tree shelters can be manufactured in accordance with
5 requirements.

It is expected that in most cases, the shelter will have an overall thickness that is in the range 1 mm to 4 mm but that in some cases could be as much as 10 mm, of which up to
10 2 mm on each side would comprise the thickness of the outer resin coating.

It will be appreciated that ideally, as soon as the resin coating has degraded to the extent that the fibrous mat
15 has become substantially exposed to environmental conditions, the shelter will thereafter disintegrate very quickly into a loose fibrous state that can form a mulch around the base of the plant, as indicated above. The fibres, then being in contact with the soil, will themselves commence a more rapid
20 biodegradation.

Hence, to this end, preferably the structure of the fibrous mat is impregnated with a second degradable resin which degrades at a different rate to that of the first
25 degradable resin under the same environmental conditions. Advantageously, the second resin encapsulates the fibres of the mat and degrades at a rate which is significantly faster than that of the first resin. For example, the first resin may take up to five years to degrade whereas the second resin
30 may be designed to degrade within six months. In such an arrangement, the degradation of the second resin enhances and speeds up the degradation of the fibrous mat, which does not need to be as rigid a structure as in embodiments of shelter where only a first resin is used. As before, preferably both
35 the first and the second resins are fully biodegradable.

- 5 -

The fibrous mat may comprise either a woven or a non-woven mat. Preferably, however, and in particular when it is desired that the mat disintegrates quickly after the first resin has degraded, the mat is non-woven. Such a mat may
5 comprises a plurality of cross-lapped layers of fibres that may be cross-linked, for example by needle-punching.

The fibrous mat may be manufactured from many different types of fibrous material but preferably is substantially
10 made from flax fibres. Other biodegradable materials that could be use instead or in addition are hemp, mineralized straw and appropriately treated grass waste.

Suitable, fully biodegradable resins for use in the
15 shelter comprise those made of polyvinyl alcohol; those made of biodegradable copolyester such as poly(tetramethylene adipate-co-terephthalate); and resins made from cashew nut shells. Such resins can all be used as the exterior covering for the fibrous mat, namely as the first resin, and there
20 life-span before degradation may be altered by addition of a UV-stabilizer. The first two resins, without the addition of any UV-stabilizer, are also suitable for use as the second resin. All of these resins biodegrade completely into non-toxic residues.

25

The resin made substantially from polyvinyl alcohol is preferably a mixture comprising between 20% and 95% polyvinyl alcohol, up to 70% calcium carbonate and between 5% and 30% propanetriol. Such a resin can be bought commercially, for
30 example from the PVAXX Group. The copolyester resin can also be bought commercially under the trade mark EASTAR from Eastman Chemical Company. Cashew nut shell resins can be bought from Palmer (UK) Limited and comprise natural renewable liquid extracted from cashew nut shells and
35 comprising a mixture of around 90% anacardic acid and 10%

- 6 -

cardol. Typically they are cross-linked with hexamine to form a solid thermosetting plastic.

Preferably also, the tree shelter comprises at least one
5 stake. Again, the stake is preferably made from a biodegradable material such as wood or cane. It may also be possible to make the stake from a mixture of the same fibres as the fibrous mat and a stiffening, degradable resin, possibly also the same as one of the resins used in the
10 manufactured of the shelter. In this case an appropriate resin/fibre ratio would be used to provide a rigid structure that would last, in use, for at least as long as the predetermined life of the shelter.

15 Advantageously, the fibrous mat can be impregnated with a slow-release fertilizer and/or a weed suppressing preparation. These impregnations are preferably designed to become active after biodegradation of the shelter. Hence, even after the tree shelter has degraded it may still have a
20 useful purpose for the formerly enclosed plant.

According to a second aspect of the present invention there is provided a method of making a tree shelter comprising the steps of: manufacturing a fibrous mat from
25 biodegradable fibres; covering the sides of the mat with a biodegradable resin; and cutting the resin-covered mat into a shape which is adapted to be formed into a self-supporting roll that can enclose at least the lower part of a plant.

30 Preferably, the fibrous mat is manufactured by carding biodegradable fibres into a loose layer; stacking a plurality of the carded fibre layers over the top of one another; and needle-punching the stacked layers to cross-link them to form the mat. The layers of fibres may be stacked in any
35 conventional manner, such as by being cross-lapped or air-blown.

Advantageously, the method comprises the additional steps of mixing a second degradable resin in powdered or granular form with the biodegradable fibres prior to
5 manufacture of the mat and of curing the second resin by heating the mat after manufacture and prior to covering by the first degradable resin.

The sides of the mat may be covered with the degradable
10 first resin by laying pre-formed sheets of the resin over the opposing sides of the mat and laminating the resin sheets and the mat together by the application of heat and pressure. Alternatively, the first resin may be extruded in a sheet form directly over each side of the mat and then cured.

15

If the first resin is in a liquid form, it may be rolled or brushed directly over each side of the mat and then cured.

20 Preferably, the resin-covered mat is cut into a substantially rectangular panel. In a first embodiment, at least one projecting tab is formed along one edge of the panel which can be inserted into a slit cut close to an opposing edge of the panel to enable the rectangular panel to
25 be formed into a self-supporting roll. Alternatively, in a second embodiment a series of slits are cut along two opposing edges of the panel through which a stake can be inserted after the panel has been formed into a roll in order to retain the shelter in a rolled state.

30

In both of the above embodiments, a stake or another stake may also be secured to the panel either by being pushed through appropriately spaced slits cut into the body of the mat or by stitching. It is also possible to secure the stake
35 by means of metal ties or rings which are simply, pushed

through the mat but these have the disadvantage of not being biodegradable and therefore unlikely to be used in practice.

Preferably also, prior to covering the sides of the mat
5 with the resin, the mat is impregnated with a slow-release fertilizer and/or a weed suppressing preparation. These impregnations may be in a powdered or granular form and mixed with the fibres or scattered between the fibre layers during manufacture of the mat.

10

It will be appreciated that the tree shelter can be made in any appropriate size. Typically, they will be made to provide, in use, an inner diameter in the range 40 mm to 250 mm, inclusive, and an height in the range 0.6 m to 1.8 m,
15 inclusive. Such shelters are suitable for use with a wide range of plants, trees and shrubs, including herbaceous plants and climbers.

The present invention will now be described by way of
20 example with reference to the accompanying drawings, in which:-

Fig. 1 is a plan view of an unrolled tree shelter according to the present invention with a portion of an outer
25 resin covering removed revealing an inner fibrous mat;

Fig. 1a is a cross-sectional view through a portion of the shelter along the line X-X in Fig.1;

30 Fig. 2 is a perspective view of the shelter shown in Fig. 1 when formed into a roll;

Fig. 3 is a perspective view of a second embodiment of tree shelter according to the present invention; and

35

Fig. 4 is a schematic view of the shelter shown in Fig. 2 when in use.

Fig. 1 shows a tree shelter 1 comprising a fibrous mat 2 and which has preferably been manufactured as described above using two resins which degrade at difference rates.

The mat 2 is preferably made from raw flax fibres 3 which after being de-baled are mixed with one of the degradable resins 4 that has been produced in a powdered or granular form. It is expected that typically the mixture will comprise around 50% flax fibre and 50% resin but the exact quantities can be varied in order that the finished mat is likely to degrade within a desired time span. As indicated above, this resin may comprise polyvinyl alcohol, poly(tetramethylene adipate-co-terephthalate), or a similar resin. If any further additive are to be included within the mat 2, such as a slow-release fertilizer this is also preferably incorporated into the mixture at this stage in a granular or powdered form.

After mixing, the fibrous mixture is carded into loose layers that are then stacked to form a plurality of carded layers, preferably by either being cross-lapped or being air-blown. These stacked layers are then cross-linked by needle-punching to form the mat 2.

The resin 4 mixed into the fibrous mat 2 is then cured by heating the mat so that the resin 4 melts and encapsulates the fibres 3.

The other resin 5 is then applied to each side of the mat 3. This resin may comprise a cashew nut oil resin, as described above, which is applied in a liquid form by brushing or rolling to form a thermosetting exterior coating

- 10 -

over both sides of the mat 2. These resin coatings 5 are then cured by again heating the mat 2 and allowing it to cool.

The final, laminated structure of the shelter 1 is shown in Fig. 1a wherein it can be seen that the mat 2 forms an inner layer and comprises a mixture of the fibres 3 and the resin 4 whereas the second resin 5 forms two outer layers which completely cover the mat 2.

10 This finished laminate structure is then cut into substantially rectangular panels 6 of a predetermined size in accordance with the size of the plant or tree to be protected.

15 In a first embodiment as shown in Figs. 1 and 2, along one of the shorter edges of the panel 6 are formed two spaced, projecting tabs 7 and along the opposing edge are cut two slits 8 that correspond to the positions of the tabs 7 so that when the panel 6 is rolled up, each tab 7 can be
20 inserted into a corresponding slit 8 to retain the panel 4 in a rolled state, as shown in Fig. 2. The tabs 7 have been shaped for this purpose by being made spoon-shaped, as shown in Fig. 1, in known fashion so that once inserted into the slits 8 they cannot easily be pulled out of position.
25 Alternatively, the tabs 7 could be made arrow-shaped.

The rolled-up panel 6 shown in Fig. 2 has been provided with two stakes 9. These stakes 9 may be fastened to the panel 6 by weaving the stakes 9 through slits 10 cut
30 appropriately in the panel 4 for this purpose. Both of the stakes 9 are used to anchor the shelter 1 to ground and one of them may also be secured to the plant being protected, as an additional support for it. Preferably, therefore, at least one of the stakes 9 is positioned so that it will be enclosed
35 by the rolled-up panel.

- 11 -

In a second embodiment, as shown in Fig. 3, the mat is cut into a rectangular panel that is provided with a plurality of slits similar to the slits 10 along two opposing edges. When the panel is rolled up, a stake 9 can be woven through the slits 10 in the overlapping portion of the panel to retain the shelter 1 in a rolled-up state before being pushed into the ground as an anchor. No additional fixing mechanism to retain the shelter in a rolled state is therefore required in this embodiment.

10

It will be appreciated that in use, the tree shelter 1 of the invention is stored and transported in panel form and only assembled into a rolled-state on site. This facilitates the storage and transportation of the shelter 1 as compared to conventional shelters which are usually manufactured in a tubular form.

In use, as shown schematically in Fig. 4, the shelter 1 is staked to the ground close to a tree or plant 11, such as a sapling, and then rolled up around the stem or trunk 12 of the plant and secured in this position using either the tabs 7 and slits 8 or one of the stakes 9 as shown in Fig. 3. The plant 11 may also be secured to one of the stakes 9, other than that used to retain the shelter 1 in a rolled state, prior to enclosure by the shelter 1. Alternatively, if the plant is not to be physically attached to the shelter 1, the shelter 1 may be folded around the stem or trunk 12 of the plant 10 and secured by means of the tabs 7 and slits 8 or the stake 9 prior to being staked into the ground.

CLAIMS

1. A tree shelter (1) comprising a biodegradable fibrous mat (2) covered with a degradable resin (5) and adapted
5 to be formed into a roll which can enclose at least the lower part of a plant.
2. A tree shelter (1) as claimed in Claim 1, wherein the fibrous mat (2) comprises a woven mat.
- 10 3. A tree shelter (1) as claimed in Claim 1, wherein the fibrous mat (2) is non-woven and comprises a plurality of layers of fibres.
- 15 4. A tree shelter (1) as claimed in Claim 3, wherein the degradable resin (5) comprises an exterior coating over each of the side surfaces of the fibrous mat (2).
- 20 5. A tree shelter (1) as claimed in Claim 4, wherein the structure of the fibrous mat (2) is impregnated with a second degradable resin (4) which degrades at a different rate to that of the first degradable resin (5) under the same environmental conditions.
- 25 6. A tree shelter (1) as claimed in Claim 5, wherein the second resin (4) encapsulates the fibres of the mat (2).
7. A tree shelter (1) as claimed in Claim 5 or Claim 6, wherein the rate of degradation of the first resin (5)
30 is longer than the rate of degradation of the second resin (4).
8. A tree shelter (1) as claimed in any of Claims 5 to 7, wherein the first and second resins (4, 5) are both
35 biodegradable.

- 13 -

9. A tree shelter (1) as claimed in any of Claims 3 to 8, wherein the layers of fibres in the mat (2) are cross-linked.
- 5 10. A tree shelter (1) as claimed in any of Claims 1 to 9, wherein the mat (2) is substantially made from at least one of or a mixture of flax fibres, hemp, mineralized straw and treated grass waste.
- 10 11. A tree shelter (1) as claimed in any of Claims 1 to 10, wherein the shelter (1) comprises a laminate structure made from two outer sheets of the first degradable resin (5) which are bonded to and enclose the fibrous mat (2).
- 15 12. A tree shelter (1) as claimed in any of Claims 1 to 11, wherein at least one of the degradable resins (4, 5) substantially comprises polyvinyl alcohol.
- 20 13. A tree shelter (1) as claimed in Claim 12, wherein said at least one resin (4, 5) is a mixture comprising between 20% and 95% polyvinyl alcohol, up to 70% calcium carbonate and between 5% and 30% propanetriol.
- 25 14. A tree shelter (1) as claimed in any of Claims 1 to 11, wherein at least one of the degradable resins (4, 5) substantially comprises a copolyester resin made from poly(tetramethylene adipate-co-terephthalate).
- 30 15. A tree shelter (1) as claimed in any of Claims 1 to 14, wherein at least one of the degradable resins (5) substantially comprises a cashew nut shell resin.
- 35 16. A tree shelter (1) as claimed in any of Claims 5 to 8, wherein the first degradable resin (5) comprising an exterior coating over the side surfaces of the fibrous mat (2) substantially comprises a cashew nut shell

resin, and the second degradable resin (4) impregnating the structure of the fibrous mat (2) substantially comprises either polyvinyl alcohol or poly(tetramethylene adipate-co-terephthalate).

5

17. A tree shelter (1) as claimed in any of Claims 1 to 16, comprising at least one biodegradable stake (9) made from the same fibres as the fibrous mat (2) and a degradable resin.

10

18. A tree shelter (1) as claimed in any of Claims 1 to 17, comprising a stake (9) which is passed through slits (10) provided in the fibrous mat to retain the shelter (1) in a rolled state when in use.

15

19. A tree shelter (1) as claimed in any of Claims 1 to 18, wherein the fibrous mat (2) is impregnated with a slow-release fertilizer and/or a weed suppressing preparation.

20

20. The use of a tree shelter (1) as claimed in any of Claims 1 to 19.

25

21. A method of making a tree shelter (1) comprising the steps of:-
manufacturing a fibrous mat (2) from biodegradable fibres;
covering the sides of the mat (2) with a degradable resin (5); and
cutting the resin-covered mat (2) into a panel (6) which is adapted to be formed into a self-supporting roll that can enclose at least the lower part of a plant.

30

35

22. A method as claimed in Claim 21, wherein the fibrous mat (2) is manufactured by
carding biodegradable fibres into a loose layer;

stacking a plurality of the carded fibre layers over one another; and

needle-punching the stacked layers to cross-link them to form the mat (2).

5

23. A method as claimed in Claim 21 or Claim 22, comprising the additional steps of mixing a second degradable resin (4) in powdered or granular form with the biodegradable fibres (3) prior to manufacture of the mat and of curing the second resin (4) by heating the mat (2) after manufacture and prior to covering by the first degradable resin (5).

10

24. A method as claimed in Claim 23, wherein the first and second resins (4, 5) are both biodegradable and the rate of degradation of the first resin (5) is longer than the rate of degradation of the second resin (4).

15

25. A method as claimed in Claim 21, wherein the fibrous mat (2) comprises a woven mat made from biodegradable yarn.

20

26. A method as claimed in any of Claims 21 to 25, wherein prior to covering the sides of the mat (2) with the first resin (5), the mat (2) is impregnated with a slow-release fertilizer and/or a weed suppressing preparation.

25

27. A method as claimed in any of Claims 21 to 26, wherein the sides of the mat (2) are covered with the degradable first resin (5) by laying pre-formed sheets of the resin (5) over the opposing sides of the mat (2) and laminating the resin sheets (5) and the mat (2) together by the application of heat and pressure.

30

- 28 A method as claimed in any of Claims 21 to 26, wherein the first resin (5) is extruding in a sheet form directly over each side of the mat (2) and then cured.
- 5 29. A method as claimed in any of Claims 21 to 26, wherein the first resin (5) is rolled or brushed in a liquid form directly over each side of the mat (2) and then cured.
- 10 30. A method as claimed in any of Claims 21 to 29, comprising the further step of cutting the resin-covered mat (2) into a substantially rectangular panel (6) along one edge of which is formed at least one projecting tab (7) that can be inserted into a slit (8) cut close to an
15 opposing edge of the panel to enable the rectangular panel (6) to be formed into a self-supporting roll.
- 20 31. A method as claimed in any of Claims 21 to 30, comprising the further step of securing at least one stake (7) to the panel (4).
- 25 32. A method as claimed in any of Claims 21 to 29, comprising the further step of cutting the resin-covered mat (2) into a substantially rectangular panel (6) along two opposing edges of which a series of slits (10) are cut and through which a stake (9) can be inserted after the panel (6) has been formed into a roll in order to retain the shelter (1) in a rolled state.
